

WCPA / IUCN

ocean acidification, which is projected to increase by 120% by 2100, will have significant impacts on coral reefs.

These changes will affect the ability of corals to build their skeletons and maintain their structures, leading to increased bleaching and mortality.

Warming oceans also contribute to sea level rise, which is projected to increase by 1-2 meters by 2100.

This rise in sea level will lead to increased flooding and coastal erosion, particularly in low-lying areas.

OECM.
